## Monday, May 06, 2019

I emailed Mr. Mattus asking him whether he made any progress on finding a laptop that can be used to demonstrate the installation of BEMOSS.

## Thursday, May 09, 2019

I picked up a department laptop from Mr. Mattus today. He cleared the partition completely, so no time had to be spent removing a previous operating system from the machine. Then, I installed Ubuntu 16.04.6 LTS on the system with a bootable USB flash from the link provided on the BEMOSS installation guide.

## Wednesday, May 22, 2019

As recommended by Dr. Miah, I worked on running BEMOSS on the previous team's laptop. By running `./startBEMOSS_GUI.sh` inside the directory `/home/bemoss/BEMOSS3.5/GUI`, I was able to start up the BEMOSS Launcher Wizard. By selecting Run BEMOSS in the TKinter GUI the server was started, and I was able to connect to the local web server at `localhost:8082..` At this point, the software was able to detect the WeMo Insight Switch and thus control the Philips Hue bulb connected to it. I was not able to control the motor due to time constraints, but I will do so soon.

I did some more research on the features that BEMOSS offers at <https://github.com/bemoss/BEMOSS3.5/wiki/BEMOSS-Features> including the ability to provide local and remote monitoring and security.

**Thursday, May 23, 2019**

## Friday, May 24, 2019

The hierarchy of BEMOSS was researched today with the motivation of understanding the software better in the Developer Resources. The first layer consists of the UI and User Management which reside in the central server. Here admins can manage different nodes on the network and either deny or accept requests from users. Layer 2 is the BEMOSS Application and Data Management Layer which allows developers to create custom applications for target devices that can be added to the UI. It may be interesting to explore this feature once I have gotten a better idea of what sort of original contributions I would like to make to the project. A motivation for this part of BEMOSS is to integrate web services like IFTTT (IF This Then That) which may be interesting to use. The third layer is the operating system and framework layer consisting of the agent platform VOLTTRON developed by the Pacific Northwest National Laboratory. Six different agents perform various different tasks such as detecting new devices (lighting/plug load controllers) on the network and monitoring them to ensure they are running properly. Layer 4 is the BEMOSS connectivity layer that handles the communication between the operating system layer and the physical hardware devices. This is where support is extended to different communication technologies like Wi-Fi, Ethernet, and Serial(RS-485). Each device supported by BEMOSS has an API translator needed to handle the differences in device attributes.

## Monday, May 27, 2019

No work was done due to Memorial Day.

## Tuesday, May 28, 2019

The outline for the presentation on May 31 follows:

- Introduction
- Applications of BEMOSS
- Hardware/software needed to install BEMOSS
- Immediate future work

The following questions are answered to determine what needs to be added to the presentation:

- What is BEMOSS? BEMOSS or Building Energy Management Open Source Software is an agent-based software platform engineered to allow small- and medium-sized commercial buildings to more seamlessly integrate equipment designed for sensing and control. This software can allow building owners and engineers to manage building energy use better by monitoring different load control devices such as lighting loads, plug loads, and HVAC controllers.
- How can BEMOSS be applied to the real world?
- What hardware and software is needed to install BEMOSS?
- What kind of future work is available to be implemented with this software?

After working on the presentation, I worked in the lab to document the toggling of the WeMo insight switch with BEMOSS. Most of this information was gathered from <https://github.com/bemoss/BEMOSS3.5/wiki/User-Guide-for-BEMOSS-UI>. Once the BEMOSS server has started, type localhost:8082 in the web browser to go to the BEMOSS Web UI. The username is 'admin' and the password is the one set during installation. To discover the switch, click the "Discover New Devices" tab in the left navigation bar. Under the "All Plug Load Controllers" menu, select either "All Plug Load Controllers" or "Belkin International Inc. Insight." Click "Discover Selected Devices" to complete the process. The number of discovered devices will appear on the Discover New Devices tab. If only one device has been discovered, a 1 will appear next to the name Discover/Manage. On the Discover/Manage page, approve the device by setting the approval status to "Approved" then select "Save Changes to Plugload Controllers." Navigate to the tab NODE1. Select "View All" under "Plugload", then select the WeMo smart plug icon to change the status of the plug and view the power consumption.

## Wednesday, May 29, 2019

I spent the first few hours of the day reading through [?]. I worked on researching the applications of BEMOSS and the introduction for the May 31st presentation. The future work still needs to be researched and added. Also, I would like to add some pictures to the slides to help the audience members gain a better visual understanding. Ideally, the presentation should be finished tomorrow morning, so I can have more time to practice. I practiced the presentation at the end of the day today without everything completed which isolated my knowledge gaps and gave me a better idea of what I should work on. To provide better flow between slides I must find ways to transition well between them.

## Thursday, May 30, 2019

More work was done on the presentation.

## Friday, May 31, 2019

Work on presentation and meeting with other members of the Robotics and Mechatronics (RAM) group.

## Monday, June 3, 2019

I read through [?] and [?] to obtain more ideas on original contributions I can make to the project. One thing I found in [?] is the use of an induction motor in McNeese State University's microgrid. With a variable frequency drive, this could be integrated with BEMOSS to control different types of industrial loads. One problem is the high price tag on both. In [?], a Particle Photon board was used to control the brightness of fluorescent lighting via step-dim ballasts. The Raspberry Pi is definitely a better option here than the Photon board as the previous senior project group used an RPi in their project.

## Tuesday, June 4, 2019

Today, I attempted to install BEMOSS on my Ubuntu laptop. After running `./startBEMOSSGUI.sh` in the GUI directory, I encountered some problems. The following errors were thrown:

Traceback (most recent call last):

```
File "Web_Server/run/defaultDB.py", line 91, in <module>
    admin = User.objects.get(username='admin')
File "/home/ramgroup/BEMOSS3.5/env/local/lib/python2.7/
site-packages/django/db/models/manager.py",
line 85, in manager_method
    return getattr(self.get_queryset(), name)(*args, **kwargs)
File "/home/ramgroup/BEMOSS3.5/env/local/lib/
python2.7/site-packages/django/db/models/query.py",
line 379, in get
    self.model._meta.object._name
```

django.contrib.auth.models.DoesNotExist: User matching query does not exist.  
OS settings imported

Traceback (most recent call last):

```
File "bemoss_lib/databases/cassandraAPI/initialize.py", line 186 in
<module>
    init()
File "bemoss_lib/databases/cassandraAPI/initialize.py", line 99, in init
    casYamlFile = open(settings.PROJECT_DIR+"/cassandra/conf/cassandra.yaml",'r')
IOError: [Errno 2] No such file or directory:
'/home/ramgroup/BEMOSS3.5/cassandra/conf/cassandra.yaml'
```

I was able to eliminate the first error by using 'admin' for the Django superuser rather than the default 'ramgroup'. I tried to eliminate the second error by deleting BEMOSS3.5 from my home directory and recloning; however, the same problem persisted. I found a directory named `/BEMOSS3.5/cassandra` on the previous group's laptop which is not being created when I run BEMOSS on my machine. This directory contains the file "cassandra.yaml" which the file "initialize.py" is attempting to access. This leads me to believing that there is some issue with the creation of the directory.

## Monday, June 10, 2019

More work was done to install BEMOSS. I emailed one of the members of the previous senior project named Bob about the error.

## Tuesday, June 11, 2019

After looking through some of the files in `/BEMOSS3.5/GUI/GUI.py`, I found the line of code preventing the installation of BEMOSS which is 108:

```
bemoss_is_installed = os.path.isdir(ui_path) and os.path.isdir(cassandra_path)
and os.path.isdir(env_path)
```

Since the cassandra directory is non-existent, the expression `os.path.isdir(cassandra_path)` evaluates as `False`.

After some further searching I found that the BEMOSS is failing to download and install the cassandra database due to a dead link in the shell script

```
/BEMOSS3.5/GUI/bemoss_install_v3.5.sh
```

When line 48:

```
wget http://downloads.datastax.com/community/dsc-cassandra-3.0.9-bin.tar.gz
```

is run, a "404 not found" error is generated by the server. The URL was entered into a web browser and it was found that the requested URL was not found on the server.

As a possible solution, I used a different URL to download the cassandra database in

```
/BEMOSS3.5/GUI/bemoss_install_v3.5.sh
```

After adding a comment on line 48, the previously mentioned URL on line 49 is changed to

```
https://archive.apache.org/dist/cassandra/3.0.9/
apache-cassandra-3.0.9-bin.tar.gz
```

Lines 49-53 were changed to

```
wget https://archive.apache.org/dist/cassandra/3.0.9/
apache-cassandra-3.0.9-bin.tar.gz
tar -xzf apache-cassandra-3.0.9-bin.tar.gz
sudo rm apache-cassandra-3.0.9-bin.tar.gz
sudo rm -rf cassandra/
sudo mv apache-cassandra-3.0.9 cassandra
```

After this, BEMOSS was successfully installed. The post-installation instructions were followed on the BEMOSS wiki, but, at the end, errors were still being thrown while attempting to get the web server up and running.

## Wednesday, June 12, 2019

After viewing the issue on the BEMOSS repo: <https://github.com/bemoss/BEMOSS3.5/issues/47>, I found that the IP address in `parent_ip.txt` did not match the IP of my system, so I changed this to the correct IP. This corrected the problem and the BEMOSS web server was able to boot successfully. Note this text file is only created after BEMOSS is run.

## Thursday, June 13, 2019

In the lab, I worked on getting BEMOSS up and running. I mistakenly used the wired connection at first when attempting to run the BEMOSS server but decided to connect to the wireless network ECE-Robotics1 as the Raspberry Pi controlling the motor uses this network. I was able to login as admin into BEMOSS but experienced a problem when attempting to connect to the WeMo Insight switch. When I attempt to navigate to the plug load page to control the WeMo switch the page does not load. It is unclear whether this is an issue with the Insight switch or with BEMOSS itself. I also tried working with the WeMo plug on the previous group's Ubuntu laptop but ran into the same issue leading me to believe it is possibly an issue with the WeMo switch.

## Friday, June 14, 2019

More work was done at the beginning of the day to help identify and fix the problem of the Plugload page not loading. After one attempt the page eventually loaded but took a great deal of time. It was finally discovered that the laptop must be connected to the wired network as well as ECE-Robotics1 in order to function properly. Without a wired connection, the PC is unable to connect to the Internet which causes errors. However, although the software was working properly errors were reported by the TSDagent. These are captured in the figure below.

```

Friday, June 14, 2019

---

I decided to try the same setup on the previous group's machine to see if I would receive the same problem. After running the software on the previous group's machine, I received the same errors with the TSDagent thus concluding that the proposed solution mentioned on page 31 is not a complete one. I will need to email Ashraf with the details on this.

In the meantime, I will attempt to get the DC motor running with the BEMOSS software. After modifying the file permissions of three of `shell_control.sh` using

```
chmod u+x shell_control.sh
```

I was able to identify and control the motor using `pyshell_control.py` which rotates the motor counter clockwise then clockwise. Soon I need to start creating the GUI that will show all devices on the network and enable the ability to control them.

## Monday, June 17, 2019

Work on the presentation slides for June 21 was done. Further research on the Beamer class was conducted to add more detail to the presentation.

## Tuesday, June 18, 2019

The presentation slides are almost complete at this point. A few more captions need to be added to the figures and sources must be added to the bibliography.

## Wednesday, June 19, 2019

Work on the presentation was continued and uploaded to github. A few additions may need to be made as I was not able to get a full 10 minutes out of it. Tonight, the presentation will be practiced and polished, so that I am ready to go by Friday. This time I need to know exactly what I am saying before going in so I can avoid any pauses.

A page on wikipedia on computer networks was read:

[https://en.wikipedia.org/wiki/Computer\\_network](https://en.wikipedia.org/wiki/Computer_network)

to better understand what is going on with this project. Knowledge of the python Tk interface must be obtained to build the GUI due June 21.

## Thursday, June 20, 2019

Had a short meeting with Dr. Miah in the lab. Here is what needs to be done:

- Add progress and plan to presentation.
- IoT discovery and control GUI and BEMOSS plugload icon must be implemented before June 28. Conference paper must be completed and submitted before June 28. However, this is not likely to be finished by then as little to no progress has been made on the GUI or BEMOSS motor integration.
- Need to start recording hours when working with the DC motor so I can get paid. I need to talk with Mrs. Polen to get an account setup with Bradley.
- I need to start thinking of a device to implement in BEMOSS. Otherwise, this project will not be successful without an original contribution. Thus, a lot of research must be done.
- Agent-based architecture will need to be researched by reading some research papers.
- Need to send Ashraf an email asking if he has made any progress on the project.

All the scripts written by Reece and Bob to control the motor were understood except for `XBEETEST.py` on the Raspberry Pi as I still need to do research on the XBee modules if I am to use them in the project.

## Friday, June 21, 2019

To better understand how to create the GUI to control the devices in the lab, I read up on the documentation for PyGTK at <https://python-gtk-3-tutorial.readthedocs.io/en/latest/layout.html#>.

## Sunday, June 23, 2019

Work was done on researching a device to integrate within BEMOSS. Here are some possible ideas:

- Ultrasonic Range Finding module - hcsr04  
I have one of these and have been programming it some and could potentially have an interesting application for IoT. However, this does seem rather simple and would not likely take long to fully implement.
- Digital Multimeter
- Accelerometer
- Gyroscope
- Dust Sensor <https://www.waveshare.com/dust-sensor.htm>
- PM2.5 Particle Sensor <https://www.cytron.io/p-honeywell-pm2.5-particle-sensor-module>  
Looking at this module it uses a two wire UART output so it would likely be very easy to interface with the Raspberry Pi

## Monday, June 24, 2019

While building the GUI, I came to realize that Gtk is simply too complex for me, so I decided to change tkinter which is a bit simpler. At this point I have finished the GUI and simply need to connect the callbacks to the events using `tk.widget.bind(event,callback)`. Once this has been done I will be ready to move on to implementing the logic to control the wemo switch and motor within the tkinter application.

## Tuesday, June 25, 2019

To better understand lower level networking concepts, I will use the python module socket to ping addresses on the network and resolve their hostnames. It may save time to use the nmap command used by the previous group; however, I would like to build a system from scratch completely in python. As the motor needs to be implemented within BEMOSS as soon as possible, I will work on this first and determine how to use the wemo switch later. I will base some of my work off [?]. However, after working for some time I found that the program I was attempting to write was rather inefficient and using the nmap command will be much more faster. Thus I have decided to use the scripts written by Bob and Reece. I was able to write a single python script using the socket module to parse through all hosts on the network 'ECE-Robotics1' and place them in a list along with their respective IP addresses.

## Wednesday, June 26, 2019

I was able to successfully add the Raspberry Pi and Wemo switch names to the listbox; however if the button 'Discover IoT Devices' is pressed continually, devices will continually be added to the list. Right now I need to determine how to initialize the Raspberry Pi by sshing into it. Then, after selecting the toggle button, I must figure out how to remotely send commands to the device to turn it on or off without having to reconnect. After some tinkering I found that I can simply just ssh into the pi and run a script that simply turns the motor on when the button is toggled on and off when the button is toggled off. Thus no initialization will be needed.

I need to write scripts to perform the following operations:

- Use nmap to scan wifi credentials
- Place the credentials into text file
- Scan for the IP addresses and place them into a text file
- Assign the address read from the file to a variable and use this to remotely login to the device (for the RPi)

However, I have almost no knowledge of bash so this will take some researching. I found a way of storing the first IP address in `IPAddresses.txt` in a variable that can be used to call the python scripts running on the pi to control the motor. Each time the toggle button is pressed, the text file is read from which is inefficient. More ideally I would like to implement some feature where the IP addresses of the devices are stored in a place that can be accessible to any shell script within the directory. I would like to do this later on; however, I need to move on to working the Wemo switch's API into this application.

To perform the implementation of the WeMo switch, I will need to read through the documentation provided by the BEMOSS team and some of the python code to find exactly what code needs to be written to create a fully functional system. This code is very complicated thus it may take a great deal of time to work through.

I found a url on the bemoss website: [www.bemoss.org/api-interface-wemo-smart-plug/](http://www.bemoss.org/api-interface-wemo-smart-plug/) that explains how some of the code works. The switch uses the upnp (Universal Plug and Play) protocol.

## Thursday, June 27, 2019

A github gist was located that contains a script to control a wemo device: <https://gist.github.com/pruppert/af7d38cb7b7ca75584ef>. I was able to successfully control the wemo switch with this. This will be helpful in understanding the code provided in the bemoss repo and on the bemoss website. The url to send commands to the switch is

`http://192.168.1.112:49153/upnp/control/basicevent1`

I attempted to add this url into the method `getDeviceStatus`; however when I run the code I receive a 500 response (internal server error). After running an nmap scan with the port scan enabled I found that the wemo switch uses both ports 53 and 49153 for communication, so the cause of the problem here is unknown. Later, I determined the problem is that no XML was being sent in the body of the POST request to the device. I simply copied the XML from the python script I found online to control the switch and modified the code from the bemoss website. This is the function used to turn on the Insight switch.

```
def turnOnSwitch():
    header = {
        'Content-Type': 'text/xml; charset="utf-8"',
        'SOAPACTION': '"urn:Belkin:service:basicevent:1#SetBinaryState"'
    }
    body='<?xml version="1.0" encoding="utf-8"?>
<s:Envelope xmlns:s="http://schemas.xmlsoap.org/soap/envelope/"
s:encodingStyle="http://schemas.xmlsoap.org/soap/encoding/">
<s:Body><u:SetBinaryState xmlns:u="urn:Belkin:service:basicevent:1">
<BinaryState>1</BinaryState>
</u:SetBinaryState></s:Body></s:Envelope>'
    controlUrl='http://192.168.1.112:49153/upnp/control/basicevent1'
    response = requests.post(controlUrl, body, headers=header)
    del response
```

To understand how this code works more research will need to be done as I know very little about XML.

## Friday, June 28, 2019

Layer 1 (UI layer) of the BEMOSS hierarchy was researched for a few hours to try and understand how new devices are to be added to BEMOSS. Details such as how the Model-Message-View-Template works and the UI project structure are provided. However, this doesn't really provide any details on what happens when an element in the UI is selected such as pressing a button to toggle a device on and how the message flows down to the device. In other words, I'm not able to understand the chain between the UI layer and the device as this is not documented on the BEMOSS wiki. A single file I found that could be possibly helpful is `/BEMOSS3.5/Web_Server/webapps/device/templates/plugload/plugload.html`. This will require some digging to understand the html, css, and jQuery as I have little to no experience in any of these. In addition, I may need to research the agent based system to understand how these agents interact with the devices' APIs.

## Monday, July 1, 2019

To understand how the device discovery agent works, I studied each line of

`BEMOSS3.5/Agents/DeviceDiscoveryAgent/devicediscovery/agent.py`

carefully. In `BEMOSS3.5/BEMOSS_lib/db_helper.py` a class named `db_connection` is defined with method `database_connect` that reads the system's ip address from `parent_ip.txt` and passes it as an argument into the method `psycopg2.connect` in order to connect to the PostgreSQL database named 'bemossdb'. Other keyword arguments that must be passed include port number, database name, user name, and database password. The full method call is

```
con = psycopg2.connect(host='136.176.122.127',port='5432',database='bemossdb', user='admin',p
```

## Tuesday, July 2, 2019

Today, I copied the file `API_WeMoPlugload.py` and renamed the copy to `API_rpi.py` in the directory `BEMOSS3.5/DeviceAPI`. However, this did not result in a new device named RPI appearing in the "Discover New Devices" page on the BEMOSS dashboard. Thus, I must do further research to determine where these names are added to the dashboard. After using the command `grep -r 'All Plug Load Controllers' .` in the directory `~/BEMOSS3.5` I was able to determine which html file places the vendor name and device model on the "Discover New Devices" page. This file is

```
/BEMOSS3.5/Web_Server/webapps/  
discovery/templates/discovery/manual_discovery.html
```

After changing the values of `'vendor_name'` and `'api_name'` in the dictionary returned by the method `API_info`, the rpi was still not appearing in the device discovery page. An error was encountered as the values corresponding to the key `vendor_name` in the copied python script `API_API_WeMoPlugloadtest` were the same as the values in the original API script `API_WeMoPlugload`. Thus it is impossible to have two devices with different vendor names and the same device model.

## Wednesday, July 3, 2019

After receiving a message from Dr. Miah, the current goal is to find a way to add a new copy of the plugload interface into the same directory as the current one and change the variables `vendor_name` and `device_model`. Following the meeting with Dr. Miah, I realized that I must work to fully understand the BEMOSS interface and the wemo switch otherwise I will not be able implement a new device successfully. This must be done by understanding the source code. I started reading through the device discovery agent source code line by line to fully understand it.

## Thursday, July 4, 2019

After making some comments in the `agent.py` file, indentation errors appeared while launching the server, the decision was made to reclone the BEMOSS repo. Progress must be made quickly today to understand the code and complete the clone of the plugload interface. I found a `try ... except` statement on lines 307 to 314 of `agent.py` that prevent the device from being detected. In a nutshell, the agent queries the PostgreSQL database with the query `SELECT * from supported_devices where vendor_name = 'Belkin International Inc.'` and `device_model = 'Insight'` when querying the Insight. If no row in the table is found, then it is determined that the device is not supported by BEMOSS.

I attempted to place a copy of the file `API_WeMoPlugload.py` in a separate directory named `research`; however, when running the file `platform_initiator.py` the database prevents a device with a duplicate key from being added.

## Friday, July 5, 2019

Several attempts to restart the server in the lab were made by recloning the repo as many errors were encountered causing the server to not startup.

## Monday, July 8, 2019

I was able to detect a new device with the copy of the wemo plug api in the second folder I made. On the device discovery page, the device name and model were the ones I declared in the `API_WeMocopy.py` file. Once the device was discovered, the vendor name and model did not match what I provided in the previously mentioned file. Plug and play discovery is never completed due to this error reported by the device discovery agent:

```
IntegrityError: duplicate key
value violates unique constraint
"device_info_pkey"\nDETAIL:
Key (agent_id)=(Insi_231707K120123A) already exists.\n\n')
```

I restarted BEMOSS to see if this was an issue due to the fact that the device had not been deleted from the device info table. Since significant alterations to the source code will likely be necessary, it was decided that the focus will now be placed on the dc motor interface now which is due July 31, 2019.

The first step I took in understanding how to add the device to the software is hardcoding a dictionary with ip address, mac address, device model (raspberrypi's username), and vendor name (Raspberry Pi Foundation). I defined these variables in a method named `discover` in the class `API` inside the module `API_PittmanMotor`. In the near future, an automated plug and play discovery process will need to be implemented but for now I would like to simply hardcode the parameters. Since I am a little lost on how the web framework used to build the platform (Django) works, I decided to watch a tutorial on it and do further research.

Django is an open source web framework. It is based on the model, view, template architecture system as explained below.

1. Model: Interact with and validate python data
2. Template: Presentation layer (html files)
3. View: Decides which template to display by interacting with the model

Project uses multiple apps to define the functionality of the site.

## Tuesday, July 9, 2019

I postponed increasing knowledge as the more important task at the moment is understanding the API translator methods such as `setDeviceStatus`, `getDataFromDevice`. After starting up BEMOSS without any code to the body of the previously mentioned functions the device was able to be successfully discovered, but the navigation bar disappeared when setting the device status to approved in the UI. Thus more configuration will be necessary to create a system that perfectly emulates the plugload interface.

As a test I ran the file `DeviceAPI/BaseAPI_WeMo.py` in a virtual environment to toggle the wemo switch. After commenting out a couple of method calls in the main function I was able to successfully toggle the device. This should be a good way of testing the raspberry pi without having to start BEMOSS everytime.

Something I found on the developer resources is that the Device Agent is responsible for handling most of the communication with the UI. It will likely be beneficial for me to read over this source code. The method `agent_setup` contains a decorator that registers the method to the callback 'onsetup' which is an event triggered at one of the agents' stages of life. Inside this method, three method calls generate callbacks to methods defined inside the `BasicAgent` class which are `updateUIBehavior`, `deviceIdentifyBehavior`, and `deviceControlBehavior`.

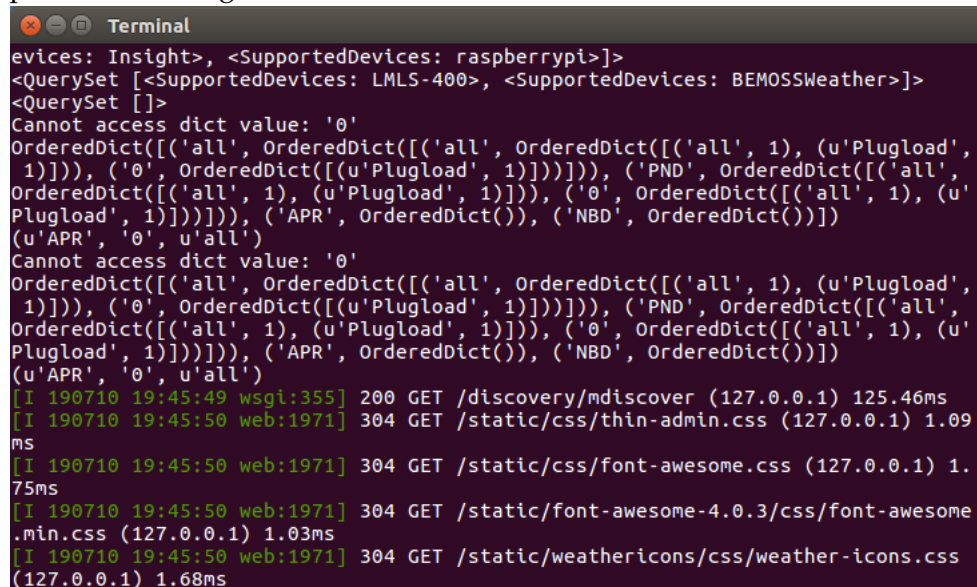

I added code to `setDeviceStatus` in the file `API_RaspberryPi.py` to ssh into the raspberry pi and run python scripts depending if the device status is set to "ON" or "OFF". Once I started up BEMOSS though I ran into some problems as I had not defined the method `getDataFromDevice`. This must return a dictionary otherwise errors will arise when displaying the data on the dashboard.

## Wednesday, July 10, 2019

The problem involving the side navigation bar not being rendered was not a result of no dictionary being returned from `getDataFromDevice`. I found that each group of the mac address must not be separated by colons; rather no delimiter is to be used at all. Once I removed the colons from the MAC address in the API file, I was able to successfully control the Raspberry Pi at my house. I wrote scripts that are able to turn on and off an led connected to one of the GPIO pins on my RPi. In the lab, it should be fairly simple to run the scripts on the RPi in the lab `XBEEON.py` and `XBEEOFF.py` to send commands to the motor in place of the scripts I use to control the LED.

A second problem still exists stemming from a `KeyError` exception in the file `Web_Server/webapps/dashboard/templatetags/device_count_in_zone.py`. I get the error `Cannot access the value, returning default: '0'` which is printed in the function `get_value_with_default` when the dictionary does not contain one of the keys passed as an argument into the function. This is shown in the screen capture below.

```

evices: Insight>, <SupportedDevices: raspberrypi>]
<QuerySet [ <SupportedDevices: LMLS-400>, <SupportedDevices: BEMOSSWeather>]>
<QuerySet []>
Cannot access dict value: '0'
OrderedDict([('all', OrderedDict([('all', OrderedDict([('all', 1), (u'Plugload', 1)])), ('0', OrderedDict([(u'Plugload', 1)]))), ('PND', OrderedDict([('all', 1), (u'Plugload', 1)]))), ('0', OrderedDict([(u'Plugload', 1)]))), ('APR', OrderedDict()), ('NBD', OrderedDict())])
(u'APR', '0', u'all')
Cannot access dict value: '0'
OrderedDict([('all', OrderedDict([('all', OrderedDict([('all', 1), (u'Plugload', 1)])), ('0', OrderedDict([(u'Plugload', 1)]))), ('PND', OrderedDict([('all', 1), (u'Plugload', 1)]))), ('0', OrderedDict([(u'Plugload', 1)]))), ('APR', OrderedDict()), ('NBD', OrderedDict())])
(u'APR', '0', u'all')
[I 190710 19:45:49 wsgi:355] 200 GET /discovery/mdiscover (127.0.0.1) 125.46ms
[I 190710 19:45:50 web:1971] 304 GET /static/css/thin-admin.css (127.0.0.1) 1.09ms

[I 190710 19:45:50 web:1971] 304 GET /static/weathericons/css/weather-icons.css (127.0.0.1) 1.68ms

```

In the lab, I was able to successfully control the motor with the plugload interface by making changes to the file `API_RaspberryPi.py`. More work was done to correct the error.

## Thursday, July 11, 2019

To test whether the new API script I wrote was the cause of the problem, I moved the file `API_RaspberryPi.py` to the home directory and restarted BEMOSS. The message `Cannot access the value, returning default: 0` was still printed to the server log at startup, so the only thing I can conclude is that this is not an issue with the new API file. As another test, I will install BEMOSS in another directory. The same messages were printed to the log when attempting to get the number of devices on the network, so at this point the messages will be ignored.

As a first step in automating the discovery process, I added the line to the method `discover` in `API_RaspberryPi.py`

```
nmap = subprocess.check_output('sudo nmap -sn 192.168.1.0/24', shell=True)
```

When this line is run, a `CalledProcessError` is thrown which removes `nmap` as an option that can be used to detect device information. The command was attempted to be run without superuser privileges; however, raw IP packets are needed to resolve MAC addresses and manufacturer names with `nmap`.

## Friday, July 12, 2019

I completed writing the discover method for the Raspberry Pi API today. A file named `ownerinfo.json` was added to the research directory where the mac address of the Raspberry Pi used to control the motor can be added. This makes identifying the correct Raspberry Pi easier as it is possible that more than one Pi could be on the network at the same time. The command `nmap` was used to ping all machines on subnet `255.255.255.0`. After this has been done information is stored in the machine's cache so that the address resolution protocol (`arp` command) may be used to find the mac addresses corresponding to the ip address on the network. After this, it is determined whether the pi's mac addresses is located in the output of the `arp -a` command.

I need to research DNS python packages to find the username of Raspberry Pi. Also, methods for storing the Raspberry Pi's password securely in the BEMOSS database must be researched.

## Monday, July 16, 2019

After doing some research I decided that I will be attempting to discover the Raspberry Pi with SSDP (Simple Service Discovery Protocol) rather than using the `nmap` and `arp` commands. Research will need to be done on these two protocols to be able to understand how to discover and control the RPi.

UPnP or Universal Plug and Play consists of three different protocols which are

- SSDP (Simple Service Discovery Protocol) for finding devices on the network
- SCPD (Service Control Point Definition) defines the actions provided
- SOAP (Simple Object Access Protocol) calls actions

I found after further research that UPnP is simply not going to work with raspberry pi as it is more designed for home media servers and not suited for my specific application which is running commands on the Pi.

## Tuesday, July 16, 2019

I attempted to run the command `sudo nmap -sn 192.168.1.0/24` in the discover method; however, I was not able to login in the volttron log terminal although the prompt for the password did appear. I attempted to launch the terminal as superuser by running the command to launch the terminal in the GUI.py as superuser. However, I ran into several issues involving privileges although I did remove the sudo prefix from the command. Now I will reinstall BEMOSS.

Rather than using both the nmap and arp commands together I made the decision to running the nmap command as superuser to resolve the manufacturer names and MAC addresses. I ran into a problem when using `subprocess.call('sudo nmap -sn 192.168.1.0/24')` as the terminal does not allow any text to be passed to stdin while the agents are running. In addition, execution of the function will continue even though system password is provided. In the end I decided to revert back to the original code as the motivation for running nmap as super user is to retrieve the mac and IP addresses.

Lastly, I found that the Raspberry Pi contains an option named Remote GPIO in the Raspi-Config which will enable the GPIO pins to be controlled over the network. No login is required to access the pins on this server only the IP address. This will hopefully streamlines tasks involving the gpio pins greatly.

## Wednesday, July 17, 2019

Following work on my presentation, I discussed with Dr. Miah using the Remote GPIO which was agreed upon. However, for the next presentation I would like to have a fully functional interface using the current method. This will require me to encrypt both the username and password of the Raspberry Pi and store in the json file that the raspberry pi API file accesses. Thus some research will need to be done on how to perform this encryption. Later (next week) I would like to get the remote GPIO interface working and implemented. Some problems still exist with this method such as security as multiple different machine may be able to control the GPIO pins at once. Also, the XBee library that is used to control the xbee modules might not be compatible with the latter method. I know very little of how zigbee communication works or how the modules work, so this will require much research.

I encrypted both the username and password of the raspberry pi by using the function `encrypt_value` in the module `bemoss_lib.utils.encrypt` and placed both these encrypted strings in the json file. I found that I needed to decrypt the values when formatting the string used to ssh into the pi. After finding that only the password must be encrypted, I replaced the username in the json file with the plain text version.

## Thursday, July 18, 2019

Today, I found that I have not implemented the method `identifyDevice` in the Raspberry Pi API. It is to be implemented as follows:

- At start, `identifyDeviceResult = False`
- Keep the current state of one of the changeable device variables (in this case the status)
- Change device variable that is visually noticeable
- Delay for 5 seconds
- Change device variable back to previous state
- if successful, `identifyDeviceResult = True`

After looking through some of the Philips Hue API code, I found that the method `get_variable` is used to check whether the device is on or off rather than directly communicating with the device through the method `getDataFromDevice` like in the WeMo plugload API. As a test I will print `get_variable('status')` in the method `identifyDevice` in the Raspberry Pi API to check whether this key value pair is in the dictionary defined in the BaseAPI's constructor. As of now, I do not know of a way of checking the status of the motor from the RPi using the GPIO pins and XBEE modules, so using the method from the Philips Hue API would be ideal.

After pressing the button `Identify Device` in the list of plugload controllers, the message logged to the console is always `'ON'`. The reason for this is likely the code I wrote in the method `getDataFromDevice` which is shown below:

```
def getDataFromDevice(self):
    # TODO
    devicedata = dict()
    devicedata['status'] = BEMOSS_ONTOLGY.STATUS.POSSIBLE_VALUES.ON
    # setting the value to "ON"
    return devicedata
```

The statement `BEMOSS_ONTOLGY.STATUS.POSSIBLE_VALUES.ON = 'ON'` is defined in the file `BEMOSS_ONTOLGY`. From the BEMOSS developer resources for layer 4 of the BEMOSS

hierarchy I found:

"Out of all the above methods, the `getDataFromDevice` method can be periodic. This means it can query and receive device data periodically. This ensures that the data are updated."

In the Basic Agent source code, a method name `deviceMonitorBehavior` is called periodically which calls `getDeviceStatus`. A call to `getDataFromDevice` occurs here which returns a dictionary and calls `convertDeviceStatus` to update the `variables` dictionary which is declared by the `BaseAPI`. Thus I must find a way to directly query the Raspberry Pi for the motor status. To start the pin mappings are between the RPi and XBee s2c module are listed below:

Raspberry Pi	XBee S2C
6 (GND)	VSS
8 (TXD)	DIN
10 (RXD)	DOUT
17 (3V3)	VCC

## Friday, July 19, 2019

In the afternoon session with the members of ram group, I experimented with the AT commands used to control the remote XBee connected to the L298N H-Bridge driver. The pin mappings are shown in the table below:

XBee	L298N
IO3	I2
IO4	I1

Also, from the L298N datasheet this table lists the DC motor control A pins and how the output of the h-bridge is effected:

EA	I1	I2	Motor A status
0	0	1	Clockwise rotation
0	1	0	Anticlockwise rotation

As a side note, the EA port is used for PWM.

However, the shaft rotations are swapped when using the motor in the lab.

## Monday, July 22, 2019

One of the AT commands use to read the digital IO of the XBee modules is the IC (Digital Change Detection) command. The command can "set or read the digital I/O pins to monitor for changes in the I/O state." When the DIO state changes, a sample can be sent immediately to the coordinator XBee from the remote XBee. However, this does not send any information on the state of the pin. The command IS "forces a read of all enabled digital and analog input lines." Of course, here a wire will be need to be connected between the output pin (IO3 or IO4) and another pin configured as a digital input. When the device needs to be queried for the status of the digital IO pins, the command IS will be sent to the remote XBee. Then using the method `XBee.wait_read_frame` I can read the data received on the UART connection from the remote XBee. Tomorrow, in the lab this will need to be experimented with.

## Tuesday, July 23, 2019

I tried using the commands mentioned in yesterday's lab notebook to no avail. This is the code I wrote to try to receive data sent from the remote XBee:

```
from xbee import XBee
import serial
import time

ser = serial.Serial('/dev/ttyS0',9600)
xbee = XBee(ser)

xbee.remote_at(
    dest_addr=b'\xff\xff',
    command='D3',
    parameter=b'\x04')
xbee.remote_at(
    dest_addr=b'\xff\xff',
    command='IS',
    parameter=b'\x03')
while True:
    try:
        print(xbee.wait_read_frame())
    except KeyboardInterrupt:
        break
```

The XCTU software was downloaded to work on configuring the remote MotorDriver XBee. IR, sample rate, was set to 1000 ms or a hex value of 0x3e8 and D1, dio1, was set as a digital input. Running `ser.read()` results in an output of `'\x00'`. Thus, no data is being received even though data should be sent to coordinator at a rate of 1 second.

## Wednesday, July 24, 2019

I decided to try experimenting with the digi-xbee python library. After following the instructions to configure the devices at

[https://xbplib.readthedocs.io/en/latest/getting\\_started\\_with\\_xbee\\_python\\_library.html#gsginstall](https://xbplib.readthedocs.io/en/latest/getting_started_with_xbee_python_library.html#gsginstall), I was unable to send AT commands to the end point XBee to toggle the

motor. This was later resolved after setting the output values of IO3 and IO4 to opposite values using XCTU. Later I was able to read the digital values of these IO lines (whether they are high or low). This means that only two IO lines will be needed to control the remote XBee module rather than 4 as the status of the IO line can be read directly even if it is a digital output. A script was written named `XBEEcontrol.py` that can toggle the motor and determine the status of the enabled pins on the remote XBEE. At the end of the day I was able to successfully identify the motor by toggling it twice with a 5 second pause inbetween. The last part of the implementation is adding the motor images to the frontend.

## Thursday, July 25, 2019

I found an picture of the GM8000 series motor and added images denoting when the motor is on and off to the `Web_Server/static/images` directory after removing the default background with GIMP.

The next task is working on adding a new device type to BEMOSS called 'Motor'. In the file `Web_Server/run/defaultDB.py`, I added the lines

```
dt5 = DeviceType(id=5, device_type='Motor')
dt5.save()
```

## Friday, July 26, 2019

Starting BEMOSS with changing the lines from yesterday result in an error when attempting to add the Raspberry Pi API to the list of the supported devices. After running the file BEMOSS3.5/Web\_Server/run/defaultDB.py by typing `python Web_Server/run/defaultDB.py` in the BEMOSS3.5 directory the problem was fixed. BEMOSS was started successfully; however, the widget listing Motors was not available on the 'Discover New Devices' page. In the file `Web_Server/webapps/discovery/views.py`, on line 58, `power_meters` was changed to `motors` and on line 71, the key value pair for the `power_meters` in the `devices` dictionary was removed and a key value pair for `motor` was added. After making further changes to the javascript and html manual discovery files, the issue was not corrected. It was later found that a closing div tag was missing from the file to close the div with class "row". Another exception was thrown when trying to access the pass usage statistics.

## Monday, July 29, 2019

The following error was thrown when running the `platform_initiator.py` file when attempting to add the motor API to the database.

```
insert or update on table "supported_devices"
violates foreign key constraint
"supported_devices_device_type_id_1f8832cb_fk_device_type_id"
DETAIL:  Key (device_type_id)=(5) is not present
in table "device_type".
```

This error is fixed by running the file `Web_Server/run/defaultDB.py` which will update the BEMOSS database. Next to help clear up the VOLTTRON log file I attempted to dissect the error message reported by the Time Series Database Agent. This error is presented below

Traceback (most recent call last):

TypeError: Object of type DefaultEndPoint is not JSON serializable  
Logged from file connection.py, line 1100

A logging issue is obviously present here and these stack traces are printed via logging message. Logging messages can have different levels of severity. In increasing order they are:

- **DEBUG:** Detailed information, typically of interest only when diagnosing problems.
- **INFO:** Confirmation that things are working as expected.
- **WARNING:** An indication that something unexpected happened, or indicative of some problem in the near future (e.g. 'disk space low'). The software is still working as expected.
- **ERROR:** Due to a more serious problem, the software has not been able to perform some function.
- **CRITICAL:** A serious error, indicating that the program itself may be unable to continue running.

The error above has level ERROR so the TSD Agent is not able to perform some function.

It appears as if some objects cannot be serialized by the python json module after some investigation. A possible fix to this problem is removing all the debug logging statements from the files in the cassandra python driver. However, this would take a great deal of time as there are many of them. Also, these logging statements are likely needed in case another problem arises. As mentioned from the log statements, on line 1100 of `cassandra.connection.py`, the following debug log statement exists:

```
log.debug("Sending options message heartbeat on idle connection (%s) %s",  
          id(connection), connection.endpoint)
```

## Tuesday, July 30, 2019

In the lab, I found that the version of the Datastax python driver used by the previous senior project group is different and only logs host names to the file rather than objects of classes defined inside the connection file. Today, I will meet with Dr. Miah to work on resolving this issue. While working on testing the motor interface I found that the power supply is not working properly. It fails to turn on immediately when the `XBEEcontrol.py` script is run with the argument `turnOnMotor`. A potential cause is the lack of a flyback diode across the input terminals to the motor which could be damaging the power supply due to voltage spikes.

In the meantime, before the meeting, I will work on trying to add plugload chart onto the motor page. Even though I am able to control the motor with the switch and identify device button, none of the data is added to the database. Something to note is that each table in BEMOSS is named according to the `agent_id`. Somewhere in the repository these tables are added to the database; however, it is unclear where that occurs. According to the BEMOSS-Data-Management section of the developer resources: "During operation, the device agents connect to the Cassandra node on the same machine the agent is running, using Cassandra python driver, and writes time series data to a unique table named after the `device_id` it is controlling."

After the meeting with Dr. Miah, it was determined that the current bug involving the cassandra python driver is a top priority. No paper will be submitted if this current issue still exists. A print statement was added on lines 133 and 139 of the `TSDAgent` source code: `print(message)`. One of the messages logged to the `volttron.log` file is

```
{u'tablename': u'platform_event', u'all_vars':  
{u'event_id': u'155df44e-e45b-4271-bc44-ce053509d22a', u'start_time':  
u'2019-07-31 04:37:42:936113*None', u'date_id': u'2019-07-30', u'agent_id':  
u'platformmonitoragent_Node1', u'end_time': u'2019-07-31  
04:38:44:552121*None'}, u'log_vars':  
{u'event_id': u'UUID', u'start_time': u'TIMESTAMP', u'date_id': u'text',  
u'agent_id': u'text', u'end_time': u'TIMESTAMP'}}
```

## Wednesday, July 31, 2019

This morning I checked the version of the cassandra-driver for python on the current machine. It is 3.18.0 and the version on Bob's machine is 3.16.0. Also, after commenting out lines 135 and 141 in Agents/TSDAgent/TSD/agent.py, the same logging error was reported to the voltron log file. Thus, the function do\_insertion\_jobs is not the only problem rather also the insert and customInsert functions. In all, the cause of this problem will be very difficult to find as there are likely many calls to methods in the cassandra-driver package. In addition, another error is reported involving the VOLTTRON bacnet proxy agent when my machine is connected to both Wi-Fi and Ethernet. This problem is resolved if the host computer is only connected to the ECE-Robotics 1 network when running BEMOSS. A screencap is posted below. A attempt to correct

```

```

the error was made by cloning BEMOSS into a new repository and ensuring the version 3.16.0 was installed rather than the latest 3.18.0. Next time, however, I need to dig deeper into the issue and understand it rather than use the "hack it until it works method". Due to time constraints, I used this method instead. The TSD agent errors were no longer present; however, another possible unrelated error was thrown by the network agent:

Traceback (most recent call last):

```

Unfortunately, as time went on the errors involving the TSD agent appeared again. At this point I have very little idea what is causing the issue. I do have a theory that the replaced URL is causing problems. So I will run a few tests:

1. Run BEMOSS with resource from old link (dsc-cassandra-3.0.9-bin.tar.gz) with cassandra-driver 3.16.0 on ramgroup laptop
2. Run BEMOSS with resource from old link (dsc-cassandra-3.0.9-bin.tar.gz) with cassandra-driver 3.18.0 on ramgroup laptop

Number 1 could not be done as the cassandra directory cannot simply be transferred from one BEMOSS directory to another when installing. After performing 2, the same TSD agent errors occurred leading me to strongly believe that this has something to do with the python cassandra driver. I will run BEMOSS again with the new link and cassandra-driver 3.16.0. The version of the cassandra-driver packaged is changed with the command `pip install cassandra-driver==version` after running the command `. env/bin/activate` to run the previous command in the BEMOSS virtual environment. After further testing I found that errors will be thrown by the time-series database agent with the cassandra-driver 3.16.0 only when BEMOSS run is run for the first time.

## Thursday, August 1, 2019

On line 2852 of cluster.py:

```
log.debug("[control connection] Opening new connection to %s", host)
```

After emailing Ashraf, the problem found yesterday is not an error as BEMOSS initializes some parameters when run the first time. So, once running the problems disappear. No more work needs to be done on this issues. The July 31 deadline was not successfully for the fully functional motor interface as the statistics chart for the motor did not appear after identifying and controlling the motor although the chart did appear one time.

I spent some time learning about VOLTTRON on <https://volttron.readthedocs.io>

## Friday, August 2, 2019

The presentation was practiced today and a few additions were made. After reading a section on Agent mobility on the VOLTTRON documentation, I decided that I would like to implement ssh key host authentication to remove the password inconvenience of controlling the raspberry pi. Running the command

```
ls .ssh
```

showed only the file known\_hosts so no private or public keys had been generated previously. Then the command

```
ssh-keygen
```

was run and the keys were placed into the ~/.ssh directory. Lastly, the command `ssh-copy-id pi@192.168.1.41` was executed to send the public key generated on the BEMOSS host machine to the RPi. A login was prompted for and the system password of the ramgroup machine was entered. After this the process was successfully completed. Now by simply running the command `ssh pi@<IP-ADDRESS>` commands can be executed. This was followed from the tutorial at

<https://www.raspberrypi.org/documentation/remote-access/ssh/passwordless.md>

## Monday, August 5, 2019

Research was done on the publish subscribe model that volttron uses to communicate between agents. Publishers (analogous to server entities) publish topics to a message queue which are then subscribed to by subscribers (analogous to clients). A subscriber can subscribe to multiple publishers and a publisher can publish to multiple subscribers. The intention was to have a Skype meeting with Ashraf at 7:00 pm cst today, but the call was never made; thus, another day much be chosen for working on completing the interface.

**Tuesday, August 6, 2019**

## Wednesday, August 7, 2019

Ubuntu 16.04 was reinstalled on the ramgroup laptop due to some package issues after attempting to install octave via the command line. The section 3 Example 2: Smart Appliance Scheduling was read in [?]. The optimal time to run a six-cycle dishwasher between 17 : 00 and 24 : 00 was analyzed with an electricity price that changes over time. The goal is to minimize

$$\sum_{k=0}^{N-1} \frac{1}{4} c_k p(x_k + u_k) u_k$$

where  $c_k$  is the electricity cost in USD/kWh,  $k$  refers to each 15 minute time period,  $N$  is the final period,  $p(x_k + u_k)$  is the power required by cycle  $x_{k+1} = x_k + u_k$ , and  $u_k \in \{0, 1\}$  is the control variable determining whether the dishwasher should maintain its cycle or move to the next cycle.

Next Monday, I will have a meeting with Ashraf about adding the new device API.

## Thursday, August 8, 2019

The principle of optimality can be expressed as the equation  $V_k(x_k)$  or the cost-to-go from time index  $k$  to  $N$ . In this problem example, the equation is

$$V_k(x_k) = \min \left\{ V_{k+1}(x_k), \frac{1}{4}c_k p(x_k + 1) + V_{k+1}(x_k + 1) \right\}$$

In other words, a decision must be made whether to continue with the last state or continue to the next state depending on which option is cheaper. Overall, conclusions were made about when the cycles of the dishwasher should be started according to when the electricity cost  $c_k$  is lowest in the given time frame. This concept can be extended to really any stateful device that uses energy in a building. Using real power cost statistics from the web, this algorithm could be implemented within BEMOSS.

## Friday, August 9, 2019

While reading the article [?], some interesting facts were discovered about BEMOSS. One is that lighting loads, plug load, and hvac controllers account for almost 75% of loads in small and medium sized buildings. In the research going forward, it would be ideal to focus efforts on implementing one of these types of devices as they have the most relevance. Section IV A. discusses the agent architecture. In a path of control agent execution, the following steps are followed:

1. Obtain the configuration for the agent which contains the agent id, agent message pub/sub address
2. Instantiate a new device API object for communicating, monitoring and controlling the device
3. Setup variables and connect with databases (time-series and metadata)
4. Monitor the status of the device with device monitor agent behavior
5. After receiving a message from the UI, one of the behaviors (UpdateDeviceStatus, DeviceControl, IdentifyDevice) is triggered

Periodically, the control agent will update its knowledge on what it knows about a device based on the setup monitoring period. The identify device behavior is for identification of a device according to its corresponding control agent. Section IV E. discusses application development. The process involves many different steps. Different examples of applications are demand response, price-based management, and load control based on local conditions. It may be interesting to implement the dynamic programming algorithm that was mentioned in the previous lab notebook entry by using demand response signals (OpenADR) from the cloud. As mentioned before, I would like to implement another either lighting, plugload or hvac controller. At first, I thought of adding a wifi enabled dimmer switch but this has actually been already added (WeMo dimmer). This was realized after looking in the script `BaseAPI_WeMo.py`. Official support has not been added yet for the device as seen on the supported device table on [www.bemoss.org](http://www.bemoss.org). Other options will need to be researched then.

A test was made to isolate the issue of the chart not appearing by configuring the motor as a plugload and running BEMOSS. The chart appeared normally.

## Monday, August 12, 2019

After the meeting with Ashraf, it was concluded that I must find how to add the new device type to BEMOSS alone as this is an open-source project and the development team only supports lighting, HVAC, and plugload controllers. In `bemoss_install_v3.5.sh`, on line 62, the `defaultDB.py` program is run which is where the device types are added to the PostgreSQL database:

```
python Web_Server/run/defaultDB.py
```

A copy of `charts_plugload.html` was added to the directory `PROJECT_DIR/Web_Server/webapps/charts/templates/charts` and renamed to `charts_motor.html`. In addition, a directory named `motor` was added in the directory `PROJECT_DIR/Web_Server/webapps/device/templates`. Inside the `motor` directory, a copy of the `plugload.html` file was added and renamed to `motor.html`. The webapp html template `manual_discovery.html` was modified by copying lines 192 to 213 and pasting them below the lines for the plug load controllers. Then, line 57 of `PROJECT_DIR/Web_Server/webapps/discovery/views.py` was changed to

```
motors = SupportedDevices.objects.filter(device_type_id=5)
```

and line 71 was changed to

```
devices = {'hvac': hvac, 'lt_loads': lt_loads,  
          'plugloads': plugloads, 'sensors': sensors, 'motors': motors}
```

With these changes, BEMOSS was restarted and tested. Then in the `API_info` method in the `API_motor.py` script, the device type id of the motor was set to 5.

Another issue appeared when no device appeared on the list supported devices on the discovery page. This was resolved by updating the html in the `manual_discovery.html` file for the motor widget.

I found another error when discovering the pittman motor. The device discovery agent receives an empty message when it subscribes to the message sent by the manual discovery views function `discover_new_devices`. This was fixed after making further changes to the django template code in `manual_discovery.html`.

Now the goal is to fix the chart issue. Some research was done in the file `PROJECT_DIR/Web_Server/webapps/charts/views.py`. Print statements were added in the `returnChartsPage` to check if some sort of exception is being thrown. In the file `charts_plugload.js` on line 80, a `TypeError` is thrown in the firefox developer console on the statistics page for the motor:

`TypeError: _status[0] is undefined`

This is the problematic javascript object:

```
axes: {
  xaxis: {
    label: "Time",
    renderer: $.jqplot.DateAxisRenderer,
    tickOptions:{formatString: '%m/%d, %H:%M'},

    min : _status[0][0],
    max: _status[_status.length-1][0]
  }
}
```

To test whether this is the cause of the problem I will change the `device_type_id` of the motor back to 3 corresponding to `plugload` as the chart appears when the device is set as a `plugload`. If the error is not shown in the console, then this must be the problem. The `_status` variable is defined in `charts_plugload.js` as `_status = {{ status|safe|list_if_none }}`; A `console.log` statement was added to determine the value of `_status`. The `status` variable is a key in the dictionary `data_dict` rendered to the page by the `charts/view.py` file by the function `returnChartsPage`. The value corresponding to `'status'` is an empty list which is the source of the issue. Tomorrow in the lab, I will check this dictionary when controlling the wemo insight switch.

## Tuesday, August 13, 2019

The result set printed to the terminal for the insight switch was similar to that printed for the motor other than the power variable. This is the variable list and result set used in the returnChartsPage function for the motor:

```
variable list:
[u'agent_id', u'date_id', u'status', u'time', u'user']
result set:
[[u'GM82_b827ebbfade' u'2019-08-13' u'None' 1565704113458
  u'device_monitor']
 [u'GM82_b827ebbfade' u'2019-08-13' 0 1565704188459 u'Admin_']]]
```

Also, this is the data dictionary rendered to the charts page by the returnChartsPage function:

```
{u'status': [], 'mac': u'b827ebbfade', 'nickname': u'Plugload2',
'node_name': u'Node1'}
```

For the Insight switch, the variable list and result set are:

```
variable list:
[u'agent_id', u'date_id', u'power', u'status', u'time', u'user']
result set:
[[u'Insi_231707K120123A' u'2019-08-13' 0.0 0 1565703938458
  u'device_monitor']
 [u'Insi_231707K120123A' u'2019-08-13' None 1 1565703963458 u'Admin_']
 [u'Insi_231707K120123A' u'2019-08-13' None 0 1565703968466 u'Admin_']]]
```

The data dictionaries are:

```
{u'status': [[1565703938458.0, 0.0], [1565703963457.0, 0.0],
[1565703963458.0, 1.0], [1565703968465.0, 1.0], [1565703968466.0, 0.0],
[1565704485071.0, 0.0]], 'mac': u'231707K120123A',
'nickname': u'Plugload1', 'node_name': u'Node1'}
{u'status': [[1565703938458.0, 0.0], [1565703963457.0, 0.0], [1565703963458.0, 1.0],
[1565703968465.0, 1.0], [1565703968466.0, 0.0], [1565704485071.0, 0.0]],
'mac': u'231707K120123A', 'nickname': u'Plugload1', u'power':
[[1565703938458.0, 0.0], [1565704485071.0, 0.0]],
'node_name': u'Node1'}
```

One difference noticed is that for all lists in the result set the status is set to None when the user is Admin\_ for the motor. In the parse\_resultset function, the line

```
x = [[lst[variables.index('time')],  
lst[variables.index(data_point)]+0.0]s  
      for lst in result_set  
      if lst[variables.index(data_point)] is not None]
```

will not return a list for each list in result\_set if the value of status is None. However, some values should still be returned as the value of status is not None when the user is Admin\_.

The reason why parse\_resultset is returning an empty list is the line

```
if len(result_set)>0 and type(result_set[0][variables.index(data_point)])  
in [str,unicode]:  
    return []
```

From the result\_set shown above,  
result\_set[0][variables.index('status')] = u'None' which is a unicode string thus the parse\_resultset function is returning an empty list. The next step I took in solving this issue is by looking in the motor api code. Since the WeMo insight switch is working perfectly, there is likely a problem with the API code I wrote for the motor. I may need to compare the two device API's to see if there are any differences. As a test I commented out the conditional statement mentioned above. This did not appear to fix the problem. From the looking at the result\_set data, once BEMOSS is started the new status values are not u'Null'. The u'Null' values were likely saved in the table when there was a mistake in the motor api code. The data in this table is still present upon restart, so a way must be found to delete the data in the table. First, I will I try to change the device type to motor rather than plugload.

The cassandraDB.py file contains a function named delete that is able to drop a table in the cassandra database. It takes a single argument, the agent id corresponding to the table to be dropped. When I called this function within a python interpreter in the PROJECT\_DIR/bemoss\_lib/databases/cassandraAPI/ directory, errors were thrown but the operation seemed to complete successfully. There seems to be some problem with this function as startDate and endDate were not specified but errors were thrown by the pandas module although they are not required. However, the table was still deleted even when these parameters were not specified. After restarting BEMOSS with tables not present in the cassandra database, the chart appeared successfully on the statistics page. Lastly, another issue still exists on the dashboard discovery page. When I press the "Set all to 'Approved'" button, the device Approval status does not update. In PROJECT\_DIR/Web\_Server/static/app\_js/discovery.js, the following code was added on lines 321 to 324:

```
$("#set_approve_Motor").click(function(e) {  
    e.preventDefault();  
    $(".app_stat_Motor").text("Approved");  
})
```

The `event.preventDefault` method will prevent the default action from being triggered and will not reload the page. This problem was not solved by performing the above action. After pressing the Save Change to Motor Controllers button, a popup is generated by firefox:

To display this page, Firefox must send information that will repeat any action (such as a search or order confirmation) that was performed earlier.

This issue was resolved by changing parenthesis and brackets of the above code as follows:

```
$("#set_approve_Motor").click(function(e) {  
    e.preventDefault();  
    $(".app_stat_Motor").text("Approved");  
});
```

## Wednesday, August 14, 2019

In a short meeting with Dr. Miah, we discussed issues with the motor. He found that something is shorting out causing the power supply to overload. This was quickly fixed by reinserting the twisted pair of wires into the screw terminals of the h-bridge driver.

Another issue with the software is when a plugload controller is discovered after discovering the motor, the nickname of the plugload controller (for example insight switch) is `plugload2` rather than `plugload1`. A likely reason is no changes were made to the html template after copying the plugload template and renaming to `motor.html`. After looking through the device discovery agent code, in the `DiscoveryAgent` constructor `self.device_num` is set to the number of devices discovered by the device discovery agent. Once a new device is discovered, in the `findDevices` method, the `self.device_num` variable is incremented, so the number after the device type refers to the total number of devices that have been discovered rather than the number of devices of the specific type that have been discovered. Later work was done on the presentation here are the topics:

- API translator discussion
- Adding a device API translator
- Adding a new device type
- Problems fixed
- Additions
- Priorities

**Thursday, August 15, 2019**

**Friday, August 16, 2019**

## Monday, August 19, 2019

In the lab, when demonstrating the motor interface to Dr. Miah, the scheduling for the motor type has not been implemented. For now, this is fine as I do not have time at the moment. Later this could be useful in scheduling the motor to turn on based on responses from the grid. During the filming of a video demonstration of the progress I have made so far, the number displaying the number of discovered devices in the discover/manage tab appears to be incorrect when both the insight switch and motor are discovered (i.e. 1 is displayed when both devices are discovered rather than 2). One of the Python files likely does not contain code for the motor controller. This is the django template code used to display the number of devices next to the label of the tab:

```
{% get_value_with_default device_count 'PND' 'all' 'all' 0 %}
```

Arguments `device_count`, `'PND'`, `'all'`, `'all'`, and `0` are passed as arguments into the template tag `get_value_with_default`. However, I do not know where `device_count` is defined. `device_count` is a dictionary returning the number of devices under each approval status such as pending, approved, or non-bemoss device.

## Tuesday, August 20, 2019

Today, I will document the full procedure for adding the motor to BEMOSS. Note PROJECT\_DIR refers to the directory containing the installation of BEMOSS. For example, ~/BEMOSS3.5.

1. Add the files BaseAPI\_RPi.py and API\_Motor.py to the directory research in the BEMOSS project directory. These are available on the Google Drive BEMOSS-Brian2019
2. In the file PROJECT\_DIR/bemoss\_lib/utils/platform\_initiator.py, replace the line `APImodule = importlib.import_module("DeviceAPI."+file)` on line 247 with  
try:

```
    APImodule = importlib.import_module("DeviceAPI."+file)
except Exception as er:
    APImodule = importlib.import_module("research."+file)
```

This will allow the platform initiator to search both the PROJECT\_DIR/DeviceAPI and PROJECT\_DIR/research directories for device API files.

3. In the discovery agent code  
PROJECT\_DIR/Agents/DeviceDiscoveryAgent/devicediscovery/agent.py,  
on line 167, replace `apiLib = importlib.import_module("DeviceAPI."+self.api)`  
with  
try:

```
    APImodule = importlib.import_module("DeviceAPI."+file)
except Exception as er:
    APImodule = importlib.import_module("research."+file)
```

to allow the basic agent to search both directories PROJECT\_DIR/DeviceAPI and PROJECT\_DIR/research for device AIP files.

4. Update the python script  
PROJECT\_DIR/Web\_Server/run/defaultDB.py with the line

```
dt5 = DeviceType(id=5, device_type='Motor')
dt5.save()
```

to register the device type Motor in the BEMOSS database.

5. Update the html template  
PROJECT\_DIR/BEMOSS3.5/Web\_Server/webapps/discovery/  
templates/discovery/manual\_discovery.html,  
by copying the html for the plugload widget and pasting below to create a widget  
for motors on the manual discovery page. Then replace the variables plugloads  
with motors and eachpl with eachmot in the copied html.
6. Update the django view  
PROJECT\_DIR/Web\_Server/webapps/discovery/views.py by replacing power\_meters  
with motors on line 58 as such  
  

```
motors = SupportedDevices.objects.filter(device_type_id=5)
```

  
On line 70 of the file, add the key value pair 'motors': motors to the devices  
dictionary that is rendered to the manual\_discovery.html file.
7. In the directory, PROJECT\_DIR/Web\_Server/webapps/device/templates copy the  
directory motor and rename to motor and rename the html template plugload.html  
to motor.html.
8. In the directory, PROJECT\_DIR/Web\_Server/webapps/charts  
/templates/charts/ copy the file charts\_plugload.html into the directory and  
rename the file to motor.html.

Note: other steps will likely be required here due to the bug regarding the number of  
devices.

## Wednesday, August 21, 2019

As a continuation of yesterday, further code must be added to the file

PROJECT\_DIR/Web\_Server/static/app\_js/manual\_disc.js

I have almost no knowledge of javascript and thus jQuery, so I do not understand this code.

The lines

```
$(".eq_height_mot").height(ht);
```

and

```
$("#mot_all").change(function() {  
    if($(this).is(":checked")) {  
        $("input[id^=mot_]").prop('checked', true);  
    } else {  
        $("input[id^=mot_]").prop('checked', false);  
    }  
});
```

must be added. Also, the expression

```
!(current_id == "mot_all")
```

must be added to line 189 of manual\_disc.js.

I will likely need to make a pdf file with these steps and place them in the Google Drive for better accessibility.

Since the RPi was automatically connecting to BUGuest, I found a tutorial online to forget the saved wifi network. By using the command,

```
sudo nano /etc/wpa_supplicant/wpa_supplicant.conf
```

the wifi network corresponding to BUGuest was deleted including the name and network block. Hopefully, this will prevent the Pi from connecting to BUGuest and only connect to ECE-Robotics1.

I found another error in the software. When clicking on the "Delete Data" button in the BEMOSS advanced settings in the advanced settings GUI, this exception is thrown:

```
Traceback (most recent call last):
  File "/usr/lib/python2.7/lib-tk/Tkinter.py", line 1540, in __call__
    return self.func(*args)
  File "GUI.py", line 385, in del_dat
    shutil.rmtree(cas_data_dir)
  File "/usr/lib/python2.7/shutil.py", line 239, in rmtree
    onerror(os.listdir, path, sys.exc_info())
  File "/usr/lib/python2.7/shutil.py", line 237, in rmtree
    names = os.listdir(path)
OSError: [Errno 2] No such file or directory:
'/home/ramgroup/BEMOSS3.5/cassandra/data'
```

The data directory is not present in the cassandra directory. For now, to delete the data from the database, I will simply just remove the table by using the function call:

```
cassandraDB.delete(agent_id)
```

where `agent_id` is the `agent_id` corresponding to the cassandra database table.

## Thursday, August 22, 2019

While researching sources for the paper, I found this source <sup>1</sup> to help me understand a little more terminology used in this project:

- Peak demand - highest average demand during a 15 period in the utility cycle
- Time-of-use pricing - electricity rate is charged based on the time of day

<sup>1</sup><https://lucidconnects.com/library/blog/electricity-demand-vs-consumption>

## Friday, August 24, 2019

A current challenge that I am facing is finding an article that discusses the vast number of electrical devices in the world such as electric vehicles, smart phones, computers, and other electrical appliances. One source I found was from the IEC - International Electrotechnical Commission.

## Tuesday, October 8, 2019

Some research was done on the kill a watt meter. The wireless version of the Kill A Watt meter - P3 4250 CO<sub>2</sub> Wireless is no longer in stock. A brochure for this device can be found at the link <http://p3international.com/brochures/p4200.pdf>. Some of the features of this device include calculation of carbon emission and energy costs by day, week, month, and year. The software controlling the wireless display can be configured to take KWh data in combination with the type of electricity generation, coal, hydroelectric, nuclear. This device may be very difficult to implement as it uses a 916.5 MHz wireless transmitter rather than a Wi-Fi interface as it is an outdated product. Additional hardware will be needed such as a receiver that can accept 916.5 MHz frequencies. The data obtained from the receiver will then need to be sent to the RPi and then to BEMOSS over Wi-Fi. In all, this device may or may not be possible to implement within BEMOSS inside the given time frame which is from now until Dec 1. Also, purchasing an outdated product that is not widely used is not advisable.

On the other hand, the P3 P4400 Kill A Watt is widely available on many different sites; however, it is not a wireless device. Thus, some soldering will need to be done and work around AC mains voltage which I personally deem to be unsafe. Mr. Mattus will also not likely allow me to work with mains voltage in the lab unless I could find a more experienced person to perform hardware modifications to the Kill A Watt. Also, a second downside to implementing this non-wireless meter is the fact that Dr. Miah prefers working with a fully functional device rather than one requiring modification.

In conclusion, I don't think that implementing either of these devices will work out as it will likely require more time than allocated to perform the task (two months).

In the meeting it was decided to work on implementing a new load whose power consumption will be monitored with the Insight Switch.

## October 15, 2019

Today, new loads were researched on the Web. Some of the openHAB documentation was read over to find any loads that could be controlled over a LAN. One obvious one is computer/server as they tend to consume a lot of energy. From the url <https://www.openhab.org/docs/configuration/items.html>, under the section on multi binding/channel linkage, interaction with an office pc is described. Network health and power consumption are monitored with a network health binding and wake-on-lan binding respectively.

More research was done on the Wake-On-LAN networking standard on wikipedia (<https://en.wikipedia.org/wiki/Wake-on-LAN>). A network message may be sent to a computer to turn on or awaken the machine. The device sending the message must be connected to the same LAN as the target PC. To implement on a wireless network, wake on wireless LAN must be used. However, after some further searching WoWLAN appears to have some serious limitations compared to WoLAN. Lastly, a computer can be in 7 different power states which are listed in Figure ???. With these states it may be possible to implement a dynamic programming algorithm to optimize the power consumption of the computer. However, I am not sure how to control these power states using the Wake on LAN, or if it is even possible.

## October 22, 2019

It was found that Wake On LAN is only able to wake computer from sleep or powered off state. Thus, more research will need to be done in order to find a way of controlling these states. At the url, <https://docs.microsoft.com/en-us/windows/win32/power/using-the-device-power-api?redirectedfrom=MSDN> I found some example c++ code of using the device power api on windows.

```
#define _WIN32_WINNT 0x0600
#include <Windows.h>
#include <PowrProf.h>
#include <stdio.h>
#include <tchar.h>

#pragma comment(lib, "PowrProf.lib")

int __cdecl main()
{
    // Define and initialize our return variables.
    LPWSTR pRetBuf = NULL;
    ULONG bufSize = MAX_PATH * sizeof(WCHAR);
    ULONG uIndex = 0;
    BOOLEAN bRet = FALSE;

    // Open the device list, querying all devices
    if (!DevicePowerOpen(0))
    {
        printf("ERROR: The device database failed to initialize.\n");
        return FALSE;
    }

    // Enumerate the device list, searching for devices that support
    // waking from either the S1 or S2 sleep state and are currently
    // present in the system, and not devices that have drivers
    // installed but are not currently attached to the system, such as
    // in a laptop docking station.
```

```
pRetBuf = (LPWSTR)LocalAlloc(LPTR, bufSize);

while (NULL != pRetBuf &&
       0 != (bRet = DevicePowerEnumDevices(uIndex,
      DEVICEPOWER_FILTER_DEVICES_PRESENT,
      PDCAP_WAKE_FROM_S1_SUPPORTED|PDCAP_WAKE_FROM_S2_SUPPORTED,
      (PBYTE)pRetBuf,
      &bufSize)))
{
    printf("Device name: %S\n", pRetBuf);

    // For the devices we found that have support for waking from
    // S1 and S2 sleep states, disable them from waking the system.
    bRet = (0 != DevicePowerSetDeviceState((LPCWSTR)pRetBuf,
      DEVICEPOWER_CLEAR_WAKEENABLED,
      NULL));

    if (0 != bRet)
    {
        printf("Warning: Failed to set device state.\n");
    }
    uIndex++;
}

// Close the device list.
DevicePowerClose();
if (pRetBuf!= NULL) LocalFree(pRetBuf);
pRetBuf = NULL;

return TRUE;
if (pRetBuf!= NULL) LocalFree(pRetBuf);
pRetBuf = NULL;
}
```

## Tuesday, October 29, 2019

Because of the small amount of time to integrate the new device (around 1 month) while only working around 2 hours per week, a different device was chosen instead of Desktop PC/server. Also, many downsides to working with these devices were found. The major problem is that the wemo switch alone can already handle shutting down and turning on a computer (although in an unideal way via hard shutdown rather than through the operating system). Secondly, switching the pc to other power states than simply off or on such as sleep or hibernate may not be possible through the operating system or using IPMI, and one of the main original motivations for implementing the remote LAN power control technologies is to control the power states. However, in the future, wake-on-lan or possibly IPMI could be implemented.

Thus, I decided to work on implementing a stepper motor to complement the DC motor worked on previously. Also, this project may be more interesting than simply turning on and off a computer remotely. The motor used is the 28BYJ-48 5V unipolar stepper motor. Some of the specs of the motor from the data sheet at <sup>1</sup> include

- 4 phases
- 1/64 speed variation ratio
- 100 Hz frequency
- 5 V DC operating voltage

At the moment, my stepper motor knowledge is limited so programming the device will require a great deal of research.

<sup>1</sup><https://download.mikroe.com/documents/datasheets/step-motor-5v-28byj48-datasheet.pdf>

## Tuesday, November 5, 2019

In addition to the stepper motor, a ULN2003A darlington transistor array is used to amplify the supply power. The IC is mounted on the ULN 2003 stepper motor driver board. I ran the python program provided in the Github repository <sup>1</sup>; and connected the stepper driver and power supply breakout board to the Raspberry GPIO extension board according to the wiring diagram provided in the file Tutorial.pdf. However, the stepper motor was not functioning at all and the LEDs on the driver board that indicate which coil is being powered were not lighting up. Also, the board became very hot to the touch when connected to the RPi and power supply module. A potential reason is the fact that a 12 V power adapter is used to power the power supply module rather than the likely recommended 5 V. A second reason is the differences between the RPi model 3 and 3B+ that I use personally. I will need to test the python script on my own raspberry Pi to see if this is the cause of any problems.

<sup>1</sup>[https://github.com/Freenove/Freenove\\_Ultimate\\_Starter\\_Kit\\_for\\_Raspberry\\_Pi.git](https://github.com/Freenove/Freenove_Ultimate_Starter_Kit_for_Raspberry_Pi.git)

## Tuesday, November 12, 2019

After the RAM group meeting on Friday Nov. 8, a member of the robot localization group commented on my idea for integrating a stepper motor. He asked about whether there was any actual way that the stepper motor can be linked to energy efficiency. To this day, I have not found a single way that the motor can be used to control a device that can help to lower energy consumption in a home or building. Over the weekend, I came upon a new IoT product on the market named the Sensibo Sky <sup>1</sup> which is a smart air conditioner controller. This product is similar to the Google Nest thermostat; however, it is used to control standalone air conditioners rather than the central HVAC system. It is capable of connecting to any air conditioner that uses an IR remote control. Some of the features of the device include 7-day scheduling, geofencing (a way determine whether occupants are in a house), control of AC unit on/off status, and fan speed. It claims to be compatible with IFTTT (If This Then That), Amazon Alexa, and Google Home. A potential challenge would be finding an air conditioner to control; for sure, it would not be feasible to work with controlling it in the lab due to potential safety risks/fire hazards. Another idea would be to control an AC unit in my own home. However, the first step will be to find a way of purchasing the Sky as the International version is fairly expensive at \$119 on Amazon.

<sup>1</sup><https://sensibo.com/products/sensibo-sky>

## Thursday, November 14, 2019

While waiting for a response from Dr. Miah about purchasing the new device, I worked on updating the motor device page by adding scheduling. The first I took was to set the variable `DEBUG` in the django web server settings file to true. This enables changes in each django application html template to be seen after refreshing the page. In addition, whenever a server-side error occurs detailed information will be displayed in the browser about where the error occurred. Before when this variable was set to false, the web server had to be restarted every time changes were made.

After uncommenting the set schedule button in the template for the motor device page named "motor.html", the following error is displayed

This message means that the `showSchedule` view function is returning an error as there is no `motor_schedule` view function defined whose output should be returned by the `showSchedule` function.

## Tuesday, November 19, 2019

Work was continued on developing the schedule app for the motor. the code in the body of the function `plugload_schedule` was copied into the new view function `motor_schedule`. However, a few modifications were made to the code by adding two new dictionaries into the file `Web_Server._utils.defaults.py` named `MOTOR_DEFAULT_SCHEDULE` and `DISABLED_VALUES_MOTOR` and replacing their `plugload` equivalents in the copied code with the new versions. Also, a new html template was added named `motor_schedule.html`. When selecting the Set Schedule button on the motor dashboard page, the following exception occurred.

```
File "/home/ramgroup/BEMOSS3.5/Web_Server/webapps/schedule/views.py" in motor_schedule
```

```
290.
```

```
    user_group = request.user.group.all().values_list('name', flat=True)
```

```
File "/home/ramgroup/BEMOSS3.5/env/local/lib/python2.7/site-packages/django/utils/functional.py" in inner
```

```
239.         return func(self._wrapped, *args)
```

Exception Type: `AttributeError` at `/schedule/b827ebbfade/`

Exception Value: `'User' object has no attribute 'group'`

I will need to research this problem as I do not know a lot about `HttpRequests` are handled in Django.

## Tuesday, February 25, 2020

Today, I worked on researching bootstrap which is a html and css framework for building responsive and resizable web pages. The following W3 Schools tutorial was followed

<https://www.w3schools.com/bootstrap4/>

Secondly, I created a simple Python http web server that I copied from this link

<https://stackoverflow.com/questions/39801718/how-to-run-a-http-server-which-serves-a-specific-file>

The code is shown below:

```
import http.server
import socketserver

PORT = 8000
Handler = http.server.SimpleHTTPRequestHandler
httpd = socketserver.TCPServer("", PORT), Handler)
print("serving at port", PORT)
httpd.serve_forever()
```

## Tuesday, March 3, 2020

Because I found that having a good foundation for the web app is nice to have first, I decided to context switch to working on the back end of the site. In this way, I can build up the project directory and setup any necessary databases. Later I can move to working on the front which (for me at least) will be a much more difficult task as I have no background in web design. Instead of using the large, more complex full-stack web framework that BEMOSS uses, Django, I will use flask as it will decrease development time. This is necessary as I only have 1 year to develop the application. First, before the project is to be setup, I will upgrade the laptop to Ubuntu 18.04 LTS from the current Ubuntu 16.04. This could potentially be a problem if I need to run BEMOSS from the laptop; however, a backup laptop is available. This tutorial from Medium was used: <https://www.cyberciti.biz/faq/how-to-upgrade-ubuntu-16-04-to-18-04-lts-using-terminal/> However, after running the command

```
sudo do-release-upgrade
```

I was notified at the end that the download will take roughly 18 minutes and the installation will take several hours, so this upgrade will have to wait for another day. At the url: <https://flask.palletsprojects.com/en/1.1.x/quickstart/#a-minimal-application>, I followed the tutorial on how to use flask. In order to render python data to an HTML template, Flask provides an interface to do this directly by using templates. Calling the function `render_template()` defined in the module flask will render to an html page provided in the first argument followed by keyword arguments to be rendered to the page. The template language in use is Jinja2.

## Monday, March 16, 2020

A break was taken from Flask work and web development to work on communicating with the ESP8266 Node MCU boards. Although full approval from the advisor has not been obtained yet, I would like to replace the XBee modules and RPi for communicating with motor. This way only one wireless communication protocol has to be used (Wi-Fi) rather than having to use two (Wi-Fi and Zigbee). I plugged in my board to the laptop which was instantly recognized as `'/dev/ttyUSB0'` by linux. Then, I downloaded the latest firmware from the URL: <http://micropython.org/download#esp8266> (the latest bin file). The tutorial at <https://docs.micropython.org/en/latest/esp8266/tutorial/intro.html> was followed to flash firmware to the device. First, the flash was erased with the command:

```
esptool.py --port /dev/ttyUSB0 erase_flash
```

However, this command threw an error stating the it could not open the port `tty/USB0` due to a permission error. This was resolved by instead using the command:

```
sudo python3 -m esptool --port /dev/ttyUSB0 erase_flash
```

Next the binary file was flashed to the chip using the command:

```
sudo python3 -m esptool --port /dev/ttyUSB0 --baud 460800 write_flash  
--flash_size=detect 0 esp8266-20191220-v1.12.bin
```

After the firmware was flashed to the board, an REPL (Read Evaluate Print Loop) was obtained over serial by running the command:

```
sudo picocom /dev/ttyUSB0 -b115200
```

This is simply a python interpreter that can run micropython. The module machine is used for performing different GPIO operations.

## Thursday, March 19, 2020

Work was done to flash a python program to the esp8266 board today. First the command `pip3 install adafruit-ampy` was used to install adafruit ampy for performing different operations on the board.

## Thursday, March 26, 2020

A simple TCP/IP web server written in python was written which will continually accept client connections and receive bytes objects. Two different LEDs are used, GPIO5 corresponding to D1 and GPIO4 corresponding to D2. Once these bytes objects are decoded as UTF-8 strings, decisions are made based on which command was sent:

- 'ON' corresponds to toggling a GPIO pin on
- 'OFF' corresponds to toggling a GPIO pin off
- 'Q' will end the client session with the server
- if an invalid command is entered the program will continue operation
- 'PWM: <int:pwm value>' corresponds to setting the PWM value of a second LED

Once 'Q' is entered by the client, the client program will end, and the server will wait to accept another connection from a client. This program was added in the script `main.py`. In order to allow `ampy` to access the serial port `/dev/ttyUSB0`, the permissions must be modified using:

```
sudo chmod 777 /dev/ttyUSB0
```

Then the command:

```
ampy --port /dev/ttyUSB0 -b115200 put main.py
```

was run to flash the program to the board.

The file `main.py` will automatically be run on board start up. To restart the program, the reset button on the board can be pressed.

To connect to the board a second program was written called `client.py` which will connect to the board with the IP hardcoded and assigned to a variable. In the future I will need a way to determine the OUI of the ESP8266 node MCU board, and determine the IP address of the board similar to the way the IP address of the RPi was determined. Once the client is connected to the server, the user will be prompted to enter a command in an infinite loop. If the string 'Q' is entered, the loop will break. The program `client.py` is designed to run on any computer capable of running python. This functionality will be implemented into the new platform by sending a command to the server whenever a button is pressed on the web page for the device.

A directory was created in the DocsBEMOSS directory named esp8266 which contains the server and client code as well as an example http server pulled from a micropython tutorial for the board available at <https://docs.micropython.org/en/latest/esp8266/tutorial/>.

PWM control was added later on to prove that it can be possible to control the speed of a motor wirelessly if speed control is desired later on.

The files `http_server.py` and `test.py` were removed from the directory esp8266/ as they contained stolen code.

## Tuesday, April 7, 2020

I created a github repository named NewBEMS for the project located at <https://github.com/blauer890/NewBEMS.git>. Later I will need to change this name; however we have not decided on a proper name for the software as of yet.

## Friday, April 17, 2020

Some of the major tasks that are required for the project were itemized in order of importance:

- Research, determine, and develop agents
- Device API/Driver development
- Microgrid Simulation
- User management

Right now I will work on determining what agents should reside in the platform. A lot of inspiration will be taken from the BEMOSS repository.

## Friday, May 1, 2020

Some work was done on the Discovery Agent today. A method named `subscribe` was added that takes a topic as a parameter and passes it to an instance of a `zmq` socket. The socket connects to tcp server `tcp://localhost:5556` which is the server used for publishing and subscribing. For now, inside an infinite loop it waits for incoming messages and prints them out. The current topic the `DiscoveryAgent` is subscribing to is `'discovery'` which could be published to from anywhere in the web app with a connection to the server. To allow the agent to perform other actions while awaiting for incoming messages, the subscriber method is started in a separate thread using the Python `threading` library.

Once a message has been received, it is parsed into the three different strings: `topic`, `method`, `args`. The `method` refers to the name of the method that is to be called on the agent object.

## Wednesday, May 20, 2020

Today, I worked on implementing the device discovery feature in the web UI. Ideally, what I would like to have is a list of devices displayed as bootstrap list-group-items with radio button embedded in them pulled right. At the bottom under the list-group, a "Find devices" button will be present which once pressed will send a message to the Device Discovery agent to start finding devices on the LAN.

Once a device or devices have been discovered, I would like to add a pop up window to showcase the devices that were discovered. With the pop up window open the background should be faded and not selectable. However, my knowledge of javascript is still pretty low, so that may take a bit of time to figure out. One change that was made to the main container is that the padding left, right, top, and bottom were all set to 20px. This way, whenever new supported devices are added the size of the container grows vertically.

As a small experiment, I ran the server on 0.0.0.0 to allow all devices on the network to access the software by changing the line in the `run.sh` script from

```
flask run
```

to

```
flask run --host=0.0.0.0
```

## Friday, May 22, 2020

Work was continued on discovery today. I need to add python code into the html template discovery.html for loading all the supported devices into the page. This will require setting up the database. I created three CREATE TABLE statements in the initialization.sql file. The tables are users, supported\_devices, and active\_devices. At the end I added a statement to add a single row into supported\_devices table. The code is posted below:

```
DROP TABLE IF EXISTS users;
DROP TABLE IF EXISTS supported_devices;
DROP TABLE IF EXISTS active_devices;

CREATE TABLE users (
  Id int NOT NULL AUTO_INCREMENT,
  Username varchar(255),
  Password varchar(255)
);

CREATE TABLE supported_devices (
  Name varchar(255),
  Manufacturer varchar(255),
);

CREATE TABLE active_devices (
  Id int NOT NULL AUTO_INCREMENT,
  Name varchar(255),
  Manufacturer varchar(255),
);

INSERT INTO supported_devices (Name, Manufacturer)
VALUES ('Insight Switch', 'Belkin');
```

Later I realized that the syntax of the code posted above is not appropriate for SQLite. Therefore, the code was changed to below:

```
CREATE TABLE IF NOT EXISTS users (  
  id INTEGER PRIMARY KEY,  
  username TEXT NOT NULL,  
  password TEXT NOT NULL  
);  
  
CREATE TABLE IF NOT EXISTS SupportedDevices (  
  name TEXT,  
  manufacturer TEXT  
);  
  
CREATE TABLE IF NOT EXISTS ActiveDevices (  
  id INT PRIMARY KEY,  
  name TEXT,  
  manufacturer TEXT  
);  
  
INSERT INTO SupportedDevices (name, manufacturer)  
VALUES ('Insight Switch', 'Belkin');
```

## Monday, May 25, 2020

I continued work on getting the devices pulled from the supported devices table into the discovery.html template via the Jinja2 template engine. In the discovery.py file which includes the view function to render data to the html file, the line `db.cursor.execute('SELECT * FROM SupportedDevices')`. However, I was having problems with the table SupportedDevices not being found in the database even though it is clearly added in the initialization.sql script I wrote. The same line was ran in the console using the flask debugger. It was found that the problem stemmed from the fact that the WebServer directory is not on the path when the server is run. This causes a problem when an attempt to connect to the database is made. Thus, the line `db = database.DBConnection('meta.db')` had to be changed to `db = database.DBConnection('./WebServer/meta.db')` where the database python module is a python file that contains the class DBConnection for performing different database operations. When the line without the relative path is specified, a file called 'meta.db' is created in the ~/NewBEMS directory. The code for the database module is shown below.

```
import sqlite3

class DBConnection:
    def __init__(self, db_name):
        self.db_name = db_name
        self.conn = sqlite3.connect(self.db_name)
        self.cursor = self.conn.cursor()

    def close(self):
        self.cursor.close()
        self.conn.close()
```

After performing this change, the discovery.html page loaded properly in the browser. Since it makes things more convenient to have the device manufacturer first and device name second, I changed around the order of these rows in the Supported Devices table. Accordingly, I updated the findDevices function used by the discovery view function for rendering supported devices to the page. Instead of using basic indexing, the string join method was used instead. The next task that needs to be completed is figuring out how to distinguish each devices each other with a unique id. The simple way of implementing this is by simpling using the entry

id INTEGER PRIMARY KEY AUTOINCREMENT

which will increment the id value every time a new row is added to the database. An elegant way of indexing each device id is by using the loop.index variable available whenever an iterable object is iterated over in an html page. For example, the code

```
{% for _ in range(3) %}
<h1>{{ loop.index }}</h1>
{% endfor %}
```

will write out the h1 headers 1,2,3. The loop.index variable can be placed as the value of an id attribute for each checkbox on the discovery page. Each id will correspond to the id of each device.

An addition to the discovery.js file will be needed to make which registers callback function for the "Search for devices" button whenever it is pressed with jQuery. The jQuery.ajax method will be used for sending an ajax request to the server to prevent the page from reloading when the submit is pressed. The code for the request is posted below:

```
$(document).ready(function() {
    $("#find_devices").click( function(evt) {
        // Prevent the default behavior from occurring.
        evt.preventDefault();
        var ids = [];
        $("input[type=checkbox]:checked").each(function() {
            ids.push($(this).attr("id"));
        });
        jsonIDs = JSON.stringify(ids)
        // alert(jsonDevices);
        $.ajax({
            url: '/discovery/ajax',
            type: 'POST', // Send a POST request
            contentType: 'application/json; charset=UTF-8',
            data: jsonIDs,
            success: function(response) {
                console.log(response);
            }
        });
    });
}); // $ here so the text after isn't green in the tex file
```

This function sends a json stringified list containing the ids of the devices to be discovered. A flask view function will be registered to the url /discovery/ajax which will publish

the data found to the discovery agent. However, the problem I am having is that when the discovery agent is started with the `run.sh` script, the terminal hangs and the web server is not able to run. Therefore, I will need to figure how to get all the agents to run from one terminal. This is solved by using the `&` operator in bash will spawn a new process for the agent to run.

## Tuesday, May 26, 2020

When I tried publishing a message to the discovery agent I got the following error:

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/home/blauer/NewBEMS/WebServer/pubsub.py", line 7, in publish
    socket.send(f"{topic} {message}".encode('utf-8'))
  File "/home/blauer/.local/lib/python3.6/site-packages/zmq/sugar/socket.py",
line 400, in send
    return super(Socket, self).send(data, flags=flags, copy=copy, track=track)
  File "zmq/backend/cython/socket.pyx", line 728,
in zmq.backend.cython.socket.Socket.send
  File "zmq/backend/cython/socket.pyx", line 775,
in zmq.backend.cython.socket.Socket.send
  File "zmq/backend/cython/socket.pyx", line 247,
in zmq.backend.cython.socket._send_copy
  File "zmq/backend/cython/socket.pyx", line 242,
in zmq.backend.cython.socket._send_copy
  File "zmq/backend/cython/checkrc.pxd", line 26,
in zmq.backend.cython.checkrc._check_rc
zmq.error.ZMQError: Operation not supported
```

I discovered that the problem lied in the parameter passed to the `zmq.Context.socket` constructor which was set as `zmq.SUB` originally but needed to be changed to `zmq.PUB`. The corrected code is posted below in the file `/NewBEMS/WebServer/pubsub.py`:

```
import zmq

def publish(topic, message, port):
    context = zmq.Context()
    socket = context.socket(zmq.PUB)
    socket.bind(f"tcp://*:{port}")
    socket.send(f"{topic} {message}".encode('utf-8'))
    socket.close()
    context.term()
```

A second problem I am having is when the function is called, the agent is not properly receiving the message. The problem only occurs when the code from the function above

is run inside of a script but not when each line is run individually using the python interpreter.

After some experimenting, I found that the message must be sent twice with a short delay (100 ms) in between in order for the message to be received by the subscriber (Discovery Agent). The message is not in fact received twice by the agent but only once by the second transmission. Therefore, the modified code is posted below:

```
import zmq
import time

def publish(topic, method, args):
    context = zmq.Context()
    socket = context.socket(zmq.PUB)
    socket.bind("tcp://*:5556")
    # The message must be sent twice to the subscriber in
    # order for it to be properly received. Not totally sure
    # why this is, possibly just the way zmq was designed.
    for _ in range(2):
        socket.send(f"{topic} {method} {args}".encode('utf-8'))
        time.sleep(0.1)
    socket.close()
    context.term()
```

After further experimenting I found that 100 ms is too short, so it was increased to 1 s with guaranteed transmission.

The next task to be completed is working on the `searchForDevices` method in the `DiscoveryAgent` class which will automatically import the corresponding API modules in the `DeviceDrivers` directory depending on the device to be discovered. Then each device will have a `findDevices` method which will search for devices on the network.

## Thursday, May 28, 2020

What needs to be done today is to do the following:

- Make the NewBEMS directory visible in the virtual environment (modify the PATH variable)
- Create a new directory called `utils` in the NewBEMS directory that will contain some helper modules for database access, etc.
- Add a text field to the supported devices table called API

Adding the NewBEMS (top level directory) to the path is as simple as adding the path

## Monday, June 8, 2020

Today, I worked on testing my DiscoveryAgent method for adding new entries to the 'ActiveDevices' table once they are discovered by the agent named setDeviceToActive. The code is posted below:

```
def setDeviceToActive(self, metadata):
    conn = sqlite3.connect('/home/blauer/NewBEMS/WebServer/meta.db')
    curs = conn.cursor()
    print('Executing cursor!')
    curs.execute("SELECT id FROM ActiveDevices WHERE name = ?;",
        (metadata['name'],))
    result = curs.fetchall()
    print(result)
    if len(result) == 0:
        try:
            print('Adding device to active devices')
            curs.execute('INSERT INTO ActiveDevices
                (name, manufacturer, macaddress) VALUES (?, ?, ?);',
                (metadata['name'], metadata['manufacturer'],
                metadata['macaddress']))
        except Exception as e:
            print("Insertion into active devices failed")
    curs.close()
    conn.close()
```

The code inside is executing; however the SQL query to insert the device into the database is failing in some way as when I run the query `SELECT * FROM ActiveDevices;` in the command prompt for the database it doesn't return any values. However, after running the query:

```
SELECT * FROM ActiveDevices;
```

in the setDeviceToActive method and calling `curs.fetchall()` the database returned the correct values.

## Friday, June 12, 2020

I read up on the linux command `readlink` that I discovered in the BEMOSS installation script in the BEMOSS3.5/GUI directory. It "prints the value of a symbolic link or canonical file name". If the command `readlink -f "$0"` is run in a shell script it prints the full path to the shell script or alternatively it can be run on the command link which prints the full path to a provided file. The objective is to determine how to connect to the meta database which lies in the WebServer directory from any file in the codebase.

Instead of using the `readlink` command, I decided to use the python function `os.getcwd()` from the `os` module as it is a much simpler way of returning the working directory of a file. I then created a file named `global_settings.py` in the base project dir which holds global string variables containing paths to all the project directories. These path constants were substituted for the full paths provided to some of the `sqlite3.connect` calls.

Next, what I would like to do is to create an installation shell script to allow anyone to clone the repository and succesfully install the current working version of the software from scratch on an Ubuntu laptop/desktop. Here's what the shell script will do

1. Assign the project directory variables
2. Update Linux (`sudo apt-get update`)
3. Install `pip3`
4. Delete the "venv" directory if it already exists
5. Create a virtual environment name "venv"
6. Activate the virtual environment
7. Use the `requirements.txt` file to install all necessary dependencies
8. Create a `directories.pth` file in the `site-packages` directory and add the directories to be added to the `PYTHON_PATH` variable to the file
9. Deactivate the virtual environment

To prevent the `TempTest/` and `venv/` directories and all `__pycache__` directories from being added, I created a `.gitignore` file with the following contents:

```
# Compiled python
__pycache__/
.pyc
.pyo

# Miscellaneous directories
TempTest/
venv/
```

However, since I am kind of still new to git, the unwanted files/directories placed in the .gitignore will not go away once the changes are pushed to the master branch. The command

```
git rm -rf --cached .
```

will unstage and remove paths from the index but keep the files in the working tree on the local disk <sup>1</sup>. A problem was encountered when running the run.sh script as I made a syntax error in an if statement.

```
./run.sh: line 17: [: missing `']
```

this code is found in the section of the script where I add the database file named meta.db which is shown below:

```
# Setup the db file
cd $webserver_dir
if [ -f "meta.db"]; then
    rm meta.db
    touch meta.db
else
    touch meta.db
fi
# $
```

After some Googling I found that I need a space between "meta.db" and the "]" character. I was able to successfully fix all the syntax errors and bugs, so now I will try to test the installation of the software on a Raspberry Pi although a VM would be perfectly acceptable as well.

<sup>1</sup><https://stackoverflow.com/questions/25436312/gitignore-not-working/25436481>

## Thursday, June 25, 2020

Today, I copied the platform files into the BEMS-LauerMiah-GitHub directory into the directory code. When I run the script to run the platform, I found that the directory code interferes with a python module in the standard library called code which enables the ability to emulate Python's interactive interpreter. One of the werkzeug libraries was throwing an exception when it tried to interpret this module as the root directory of the project was named the same. After renaming the directory to NewBEMS everything appeared to work fine. Also, I changed the operator '>' to '»' in the install.sh script to append to the .pth files rather than over write.

## Friday, June 26, 2020

The tasks for today are the following:

- Implement a feature to allow the Device Discovery agent to loop a set number of times and call the `find_devices` function for each supported device API module.

I decided that the modal popup is not really necessary if auto discovery will be enabled by default as the devices will simply show up on the page and the user will not need to be notified of this through a modal. I problem I ran into is the fact that the web pages are not uploading despite removing the modal button and popup being removed from the `discovery.html` page. It was found that I was running the server from the wrong directory as I have the software installed in my home directory.

## Tuesday, June 30, 2020

The problem I was having the problem of svgs not rendering in Chrome as I would like to add an icon made in inkscape for each device.

## Wednesday, July 1, 2020

After changing a line in the svg file created by inkscape, the image properly rendered in chrome. Today, I worked on reworking the discovery process by eliminating the search for device page and just having a single page for active devices. Also, I added some HTML to display a message when no devices are found on the network. I created a second python flask view function module `active_devices.py` which will handle urls to the `active_devices` page rather than the discovery page. I simplified the discovery process by having a single method titled `searchForDevices` in the `DiscoveryAgent` class which will simply perform the following actions:

- Pull apis from the `SupportedDevices` table
- Import each API module corresponding to that API
- Call `findDevices` on each API module and assign the url list to a variable
- Retrieve the metadata from each list
- Add metadata to the `ActiveDevices` table
- Send post request to the server to get the active devices from the table and render to the UI

The problem I am trying to solve now is how to get an update from the agent when it has completed discovering devices. What this will require is sending a message to the UI. A solution to this problem is by simply returning a tuple from a flask route <sup>1</sup>. The response will be empty with a status of 204 (no response). Even though it may not be the best implementation, I decided to add a global variable `done_discovering` which will be set to true when a request has been sent to the url `/active_devices/agents` by the `DiscoveryAgent` and the `renderActiveDevices` function will constantly wait for it to be set to True before rendering data to the html page.

A problem I am running into is the fact that the Discovery Agent is adding devices to the `ActiveDevices` table. However, when the following query is made by the flask backend:

```
SELECT * FROM ActiveDevices;
```

<sup>1</sup><https://stackoverflow.com/questions/24295426/python-flask-intentional-empty-response>

it returns an empty list. Although changes were made shortly before it to add devices to the table. The mistake I made was forgetting to include the statement:

```
conn.commit()
```

which commits the changes to the database after inserting into the `ActiveDevices` table.

The next task is to add a collapsible accordion to the `active_devices` page to display all the devices that can be controlled in one page <sup>2</sup>. In addition, I added a column to the `ActiveDevices` table, `image`, which will contain a string specifying an `svg` in the `static/img` directory.

<sup>2</sup><https://getbootstrap.com/docs/4.3/components/collapse/>

## Monday, July 6, 2020

What I worked on today was getting the on/off switch to work for the WeMo Switch. First, I added a method to the control agent titled `setDeviceStatus`. Since this method will be required to call the `setState` method of the device that requests it, an `api` column is required in the `ActiveDevices` table. Then, the module will be imported using the built in `importlib` module by calling `import_module`. Since I realized that the `url` is required to be passed in to the `setState` function of the `WeMoAPI`, I decided to instead add two more fields to the active devices table titled `ip` and `port`. The `url` will be parsed using `urllib.parse.urlparse`. Then different properties can be referenced from the returned object such as the `scheme`, `netloc`, `path`, `parameters`, `query`, and `fragment`. Using the following code:

```
from urllib.parse import urlparse
parsedUrl = urlparse(url)
netLocation = parsedUrl.netloc
netLocationList = netLocation.split(':')
ip = netLocationList[0]
port = netLocationList[1]
```

the `ip` and `port` is obtained. I replaced `url` as the first argument to the `setState` function with `deviceId` which will be the id of the target device.

## Tuesday, July 7, 2020

I worked on getting JQuery code added to the active devices page by adding a file titled `active_device.js` with the following function:

```
$(document).ready(function() {  
    $('input[type="checkbox"]').click(function(evt) {  
        evt.preventDefault();  
        var dict = {};  
        dict["id"] = $(this).attr("id");  
        if($(this).prop("checked") == true) {  
            dict["powerState"] = "ON";  
        } else if ($(this).prop("checked") == false) {  
            dict["powerState"] = "OFF";  
        }  
        jsonDict = JSON.stringify(dict)  
        $.ajax({  
            url: '/active_devices/ajax',  
            type: 'POST',  
            contentType: 'application/json; charset=UTF-8',  
            data: jsonDict,  
            success: function(response) {  
                console.log(response);  
            }  
        });  
    });  
});
```

Essentially, when a device is pressed the corresponding id of the device is the id of the button element. Then, the state of the device is assigned to the key "powerState" whether it be "ON" or "OFF". This dictionary is sent with the powerState and id key/value pairs as a json encoded string to the server. However, the click function does not appear to be called when the toggle button is clicked. When the data-toggle attribute of the input element described below:

```
<input type="checkbox" id="wemo" data-onstyle="success" data-toggle="toggle">
```

is removed, the checkbox no longer becomes a bootstrap toggle checkbox but rather a normal checkbox. This does solve the problem of the on click listener not working properly in JQuery though. Therefore, it must be determined how to properly listen for onclick events from the bootstrap toggle button.

## Wednesday, July 8, 2020

I was able to get the bootstrap toggle function to be detected with javascript using the change method:

```
$('#input[type="checkbox"]').change(function() {  
    if($(this).prop("checked") == true) {  
        console.log("checked true");  
        console.log($(this).attr("id")); //$  
    }  
    console.log("clicked");  
});
```

A function similar to the one above was written to send an AJAX request to the backend.

```
$('#input[type="checkbox"]').change(function() {  
    // evt.preventDefault();  
    console.log("Changed checkbox");  
    var dict = {};  
    dict["id"] = $(this).attr("id");  
    if($(this).prop("checked") == true) {  
        dict["powerState"] = "ON";  
    } else if ($(this).prop("checked") == false) {  
        dict["powerState"] = "OFF";  
    }  
    jsonDict = JSON.stringify(dict)  
    console.log(dict);  
    console.log(jsonDict);  
    $.ajax({  
        url: '/active_devices/ajax',  
        type: 'POST',  
        contentType: 'application/json;charset=UTF-8',  
        data: jsonDict,  
        success: function(response) {  
            console.log(response);  
        }  
    });  
}); //$
```

A potential problem I see in using publish/subscribe in sending data to agents is the fact that the following exception is thrown if the toggle button is pressed too frequently:

```
zmq.error.ZMQError: Address already in use
```

as multiple publishes are being attempted using the same address. The line

```
python3 ControlAgent.py &
```

which will run the Control Agent. However, a problem exists in the subscribe method as the message received from the web server:

```
self.msg = socket.recv().decode('utf-8')
```

does not unpack to three different strings when using the line

```
topic, method, args = self.msg.split()
```

as args is a dictionary which contains a space.
